Transactional Memory. Foundations, Algorithms, Tools, and Applications Rachid Guerraoui, Paolo Romano, 2014-12-29 The advent of multi core architectures and cloud computing has brought parallel programming into the mainstream of software development Unfortunately writing

scalable parallel programs using traditional lock based synchronization primitives is well known to be a hard time consuming and error prone task mastered by only a minority of specialized programmers Building on the familiar abstraction of atomic transactions Transactional Memory TM promises to free programmers from the complexity of conventional synchronization schemes simplifying the development and verification of concurrent programs enhancing code reliability and boosting productivity Over the last decade TM has been subject to intense research on a broad range of aspects including hardware and operating systems support language integration as well as algorithms and theoretical foundations On the industrial side the major players of the software and hardware markets have been up front in the research and development of prototypal products providing support for TM systems This has recently led to the introduction of hardware TM implementations on mainstream commercial microprocessors and to the integration of TM support for the world s leading open source compiler In such a vast inter disciplinary domain the Euro TM COST Action IC1001 has served as a catalyzer and a bridge for the various research communities looking at disparate yet subtly interconnected aspects of TM This book emerged from the idea having Euro TM experts compile recent results in the TM area in a single and consistent volume Contributions have been carefully selected and revised to provide a broad coverage of several fundamental issues associated with the design and implementation of TM systems including their theoretical underpinnings and algorithmic foundations programming language integration and verification tools hardware supports distributed TM systems self tuning mechanisms as well as lessons learnt from building complex TM based applications

*Compiler Analysis to Implement Point-to-point Synchronization in Parallel Programs* John Nguyen, 1993 Abstract The shared memory data parallel model presents an attractive interface for programming multiprocessors by allowing for easy management of parallel tasks while hiding details of the underlying machine architecture Unfortunately the shared memory abstraction requires synchronization in order to maintain data consistency Present compilers provide consistency between parallel code sections by enforcing a global point of synchrony with a barrier synchronization Such a simple mechanism possesses several disadvantages First the required global collection of information generates significant overhead which leads machine designers to employ special hardware to support barriers Second global synchronization reduces parallelism by requiring needless serialization of independent tasks This work aims to reduce the costs associated with these disadvantages by generating pairwise point to point synchronization between specific tasks Implementation of point to point synchronization demands extensive analysis of program dependences A compiler must perform flow analysis and dependence testing in order to compute lexical dependences between program statements In addition dynamic dependences between processors must be computed by examining array reference and statement contexts The final synchronization scheme must support any dependences that arise in the program while ensuring that no deadlock scenarios can occur This work proposes algorithms that satisfy such requirements and presents some encouraging results from a preliminary implementation

Zucker,1991 Abstract Efficient synchronization is a key element in obtaining good speed up from parallel programs The overhead introduced by synchronization especially lock manipulation can sometimes remove any benefit from parallelizing programs

Techniques to efficiently obtain locks under high contention have been studied in the literature using artificial programs. We consider the impact of these techniques in a more realistic framework using a sample of real parallel programs running on a shared bus multiprocessor system. Cycles lost to lock contention and the number of processors waiting to acquire a lock are the two principal metrics that we use. Trace driven simulation experiments are performed for sequentially consistent and weakly consistent architectural models.

**Static Analyses and Optimizations for Parallel Programs with Synchronization** Yuan Zhang, 2008

As parallel systems become dominant in computer architectures, parallel programs that take the advantage of multiple threads of control are taking the place of conventional sequential programs. Yet parallel programs have introduced new challenges to compiler static analyses and optimizations. On one hand, classical compiler analyses and optimizations need to be enhanced to handle the inter-thread interference and synchronization enforced dependence relation in a parallel program. On the other hand, new analyses and optimizations need to be designed for new programming language features. In this dissertation, we propose the following compiler static analyses and optimizations for parallel programs with synchronization:

1. An interprocedural multi-valued expressions analysis for both distributed and shared memory programs based on program slicing. An expression is multi-valued if it evaluates differently in different threads. For Single Program Multiple Data style programs, multi-valued expressions analysis is a key component to determine the concurrent paths which are executed by different threads concurrently.
2. An interprocedural barrier matching technique for both distributed and shared memory programs to detect synchronization errors caused by the misplacement of barriers or if the program is validated to determine the set of barrier statements that synchronize together.
3. The first interprocedural concurrency analysis algorithm that can handle shared memory programs with textually unaligned barriers.
4. A new framework of flow-sensitive and synchronization-sensitive data flow analyses for shared memory programs. Pointer analysis is used as an example to demonstrate the effectiveness of this framework. The most significant advantage of this framework is that inter-thread interference and synchronization enforced dependence are modeled as concurrency relation; thus, it is easily extensible to new language features and compatible with different memory models.
5. A lock assignment algorithm to optimize shared memory programs with atomic sections: a high productivity synchronization construct that enforces atomicity and mutual exclusion. Taking a program annotated with atomic sections, the compiler automatically infers an assignment of the minimum number of locks to atomic sections so as to exploit the parallelism among atomic sections without violating their semantics.

Two additional lock optimization problems that are closely related to the lock assignment problem are presented.
