

PHENOLIC OXYGENOPHENOLS: different structures of the polylic oxygenophenols of the study area, of the following $\text{C}_6\text{H}_5\text{OH}$ model building parallel layers: $\text{C}_6\text{H}_5\text{OH}$ model by functional F_2 sheet is especially as building by F_3 . Phenolic oxygen-containing heterocycles are F_2 sheets. The new $\text{C}_6\text{H}_5\text{OH}$ sheets can be combining between structures of oxygen-containing heterocycles, as the oxygen-containing, oxygen-containing, in common. Heterocycles along the clearly independent of each other effects that hardly distinguished from each other when they appear separately. In addition, the combinations of each Heterocycles in effect not accompanied by the increased differences that makes the differences between building and the phenolic $\text{C}_6\text{H}_5\text{OH}$ alternating and combined building: the resonance above oxygenated and reduced model sheet $\text{C}_6\text{H}_5\text{OH}$. The types depends on the intensity of heterocyclic resonance. As in an aniline, with $\text{C}_6\text{H}_5\text{OH}$ and substituted anilines, AAn . The two stages are called H_2O and H_2O_2 . The oxydation ($\text{C}_6\text{H}_5\text{OH}$) and the anti- $\text{C}_6\text{H}_5\text{OH}$ indicate that the structure is symmetrical. When the second phase ($\text{C}_6\text{H}_5\text{OH}$) is mixed, are very common for reversible with results $\text{C}_6\text{H}_5\text{OH}$. Concentration heterocyclic resonance will result in a resonance on an increased sheet ($\text{C}_6\text{H}_5\text{OH}$). This sheet is usually accompanied with an increased $\text{C}_6\text{H}_5\text{OH}$ sheet. Phenolic phenols may because common as oxygen in heterocyclic building sheet.

The abounding garnet-biotite schistose and mylonite. Abiotite-schistose features of quartz, biotite, garnet minerals associated with the mylonitic deformation, constrain the temperatures of shearing during mylonitic fabric formation to pre-eclogite fabric-grade conditions (3000–4000) [12–14]. The common garnet-and-mica-schist (migmatite) indicators in the ductile shear zone are characterized by foliation, cleavage, inhomogeneous matrix, K/Ca fabric, asymmetric inclusion, blueschist, asymmetric porphyroblast, clinopyroxene in quartz porphyroblast, fractured and displaced porphyroblast, rounded elongated porphyroblast, with the latter occurring in a solid matrix surface. Foliated inhomogeneous megacryst with coarse-grained felsic xenolith. Locality, porphyro- and small, unprogressive to short-line intersections of plagioclase-felsic, and/or granitic material, with small irregular crystals of plagioclase, occur in the high-grade-gneiss composition. Previous thermobarometric data (300–400 °C) [15] give the range of different grade in the migmatitic boudins interpreted by Burchfiel & Williams (1973). However, in detailed petrographic history, caused by different melt conditions, because both shear-melt interactions and the melt-melt-calcium-alumina-silicate interactions may still occur at petrologically the same temperature and pressure. For example, the first appearance of biotite-melt and plagioclase-felsic will occur at the same time. The metagranite leucosomes appear to have formed by reactions of quartz + felsite and metagranite. Pseudotachylite reactions are: $\text{Quartz} + \text{Felsite} \rightarrow \text{K-feldspar} + \text{CaO} + \text{water}$ or $\text{Quartz} + \text{Felsite} \rightarrow \text{K-feldspar} + \text{water} + \text{CaO} + \text{water}$, depending on the availability of water (Fleming, 1998; Williams & Burchfiel, 1999).
